METHOD AND DEVICE FOR PERFORMING TRANSMISSIONS OF DATA

TECHNICAL FIELD

[0001] The present invention generally relates to determining, in a distributed fashion, precoders to be applied for transmitting data between a plurality of transmitters and a plurality of receivers in a MIMO channel-based wireless communication system.

BACKGROUND ART

[0002] Wireless communication systems may rely on cooperation in order to improve their performance with regard to their environment. According to one example, such cooperation can be found in a context of a MIMO (Multiple-Input Multiple-Output) channel-based communications network in which node devices, typically access points such as base stations or eNodeBs, cooperate in order to improve overall robustness of communications via the MIMO channel.

[0003] So as to perform such cooperation, transmitters of a considered wireless communication system rely on CSI (Channel State Information) related data and/or channel estimation related data for determining a precoder to be applied by said transmitters in order to improve performance of transmissions via the MIMO channel from said transmitters to a predefined set of receivers. Such a precoder is typically determined in a central fashion, and parameters of the predetermined precoder are then propagated toward said transmitters for further applying said determined precoder during transmissions via the MIMO channel from said transmitters to said receivers.

[0004] It would be advantageous, in terms of system architecture and in terms of balance of processing resources usage, to provide a method for enabling determining the precoder parameters in a distributed fashion among the transmitters. However, doing so, CSI (CSI at Transmitter) mismatch generally appears. This may involve a significant divergence between the precoder parameters computed by the transmitters on their own. The performance enhancement targeted by the cooperation is therefore not as high as expected, since the precoder parameters independently determined by the transmitters involve residual interference that grows with the CSI mismatch.

[0005] It is desirable to overcome the aforementioned drawbacks of the prior art. It is more particularly desirable to provide a solution that allows improving performance of transmissions from a predefined set of transmitters toward a predefined set of receivers in a MIMO-channel based wireless communication system by relying on a precoder determined in a distributed fashion among said transmitters, although CSI mismatch may exist.

SUMMARY OF INVENTION

[0006] To that end, the present invention concerns a method for performing transmissions of data between a plurality of K transmitters and a plurality of K receivers via a global MIMO channel \( \mathbb{H} = \{ H_1, \ldots, H_K \} \) of a wireless communication system, by determining in a distributed fashion precoders to be applied for performing said transmissions, said precoders being respectively applied by said transmitters and jointly forming an overall precoder \( V \), wherein each and every j-th transmitter among said plurality of K transmitters performs: gathering long-term statistics of Channel State Information at Transmitter CSIIT errors incurred by each one of the K transmitters with respect to the global MIMO channel \( \mathbb{H} \), the long-term statistics describing the random variation of the CSIIT errors; obtaining short-term CSIIT related data and building its own view \( \mathbb{H}_j \) of the global MIMO channel \( \mathbb{H} \); determining an estimate \( \hat{V}_j \) of the overall precoder \( V \) from the obtained short-term CSIIT related data; refining the estimate \( \hat{V}_j \) by \( \hat{V}_j(\hat{X}_1, \ldots, \hat{X}_K) \) of the overall precoder \( V \) via the basis of the gathered long-term statistics of CSIIT errors so as to obtain a refined precoder \( \hat{V}_j(\hat{X}_1, \ldots, \hat{X}_K) \) which is a view of the overall precoder \( V \) from the standpoint of said j-th transmitter, further on the basis of its own view \( \mathbb{H}_j \) of the global MIMO channel \( \mathbb{H} \), and further on the basis of a figure of merit representative of performance of said transmissions via the global MIMO channel \( \mathbb{H} \) and transmitting the data by applying a precoder that is formed by a part of the refined precoder \( \hat{V}_j(\hat{X}_1, \ldots, \hat{X}_K) \) which relates to said j-th transmitter among said plurality of K transmitters.

[0007] Thus, performance of transmissions via the global MIMO channel of the wireless communication system is improved by relying on a precoder determined in a distributed fashion, although CSIIT mismatch may exist. Robustness against CSIIT mismatch is thus achieved without needing a central unit to compute the precoder.

[0008] According to a particular feature, the figure of merit is a lower bound of a sum rate \( \text{LBSR} \) reached via the global MIMO channel \( \mathbb{H} \) from the standpoint of said j-th transmitter with respect to its own view \( \mathbb{H}_j \) of the global MIMO channel \( \mathbb{H} \), as follows:

\[
\text{LBSR} = \sum_{k=1}^{K} \log i \left( \det \left( \text{EMSE} (F_1, \ldots, F_K) \right) \right)
\]

wherein \( \text{EMSE} (F_1, \ldots, F_K) = E \{ (a(1), \ldots, a(2)) \} \text{MSE}(F_1, \ldots, F_K) \}
\]

wherein \( \mathbb{E} \) represents the mathematical expectation and, wherein \( \text{MSE}(F_1, \ldots, F_K) \) represents mean square error matrix between the data to be transmitted and a corresponding filtered received vector for a realization of estimate errors \( \Delta^{(1)}, \Delta^{(2)}, \ldots, \Delta^{(K)} \) which matches the long terms statistics of CSIIT errors.

[0009] Thus, the sum of the rates of the receivers served by said transmissions is improved by the determined precoder.

[0010] According to a particular feature, the figure of merit is the sum of traces \( \text{MINMSE} \), for \( k = 1 \) to \( K \), of \( \text{MSE}_{k} (F_1, \ldots, F_K) \) as follows:

\[
\text{MINMSE} = \sum_{k=1}^{K} \text{Trace} \{ \text{EMSE} (F_1, \ldots, F_K) \}
\]

wherein \( \text{EMSE} (F_1, \ldots, F_K) = E \{ (a(1), \ldots, a(2)) \} \text{MSE}(F_1, \ldots, F_K) \}
\]

wherein \( \mathbb{E} \) represents the mathematical expectation and, wherein \( \text{MSE}_{k} (F_1, \ldots, F_K) \) represents the mean square error matrix between the data to be transmitted and a
corresponding filtered received vector for a realization of estimate errors $\Delta^{(1)}, \Delta^{(2)}, \ldots, \Delta^{(K)}$ which matches the long term statistics of CSIT errors.

[0011] Thus, the average mean square error, as perceived by the receivers is improved by the determined precoder.

[0012] According to a particular feature, refining the estimate $\hat{V}^{(0)}$ of the overall precoder $V$ is performed thanks to a refinement function $f(\ldots)$, as well as a set $\{F^{(0)}_k\}$ of refinement matrices $F^{(0)}_k, k=1$ to $K$, in a multiplicative refinement strategy, as follows:

$$v^{(0)}_{\text{est}} = f(v^{(0)}, F^{(0)}_k v^{(0)}), k=1 \text{ to } K$$

[0013] Thus, such a multiplicative refinement allows for correcting CSIT mismatch, especially in the context of block diagonalization precoding.

[0014] According to a particular feature, the overall precoder $V$ is a block-diagonalization precoder, the transmitters have cumulatively at least as many antennas as the receivers, and refining the estimate $\hat{V}^{(0)}$ of the overall precoder $V$ thus consists in optimizing the set $\{F^{(0)}_k\}$ of the refinement matrices $F^{(0)}_k$ with respect to the set $\{\hat{V}^{(0)}\}$ of the matrices $\hat{V}^{(0)}$, which is obtained by applying a Singular Value Decomposition operation as follows:

$$\hat{V}^{(0)} = FT^{(0)}_k P^{(0)}_k, k=1 \text{ to } K$$

wherein $T^{(0)}_k$ represents a view of an aggregated interference channel estimation $\hat{H}^{(0)}_k$ for the k-th receiver among the $K$ receivers from the standpoint of said j-th transmitter, with

$$\hat{H}^{(0)}_k = [\hat{H}^{(0)}_{k,1}, \ldots, \hat{H}^{(0)}_{k,j-1}, \hat{H}^{(0)}_{k,j}, \ldots, \hat{H}^{(0)}_{k,K}]$$

wherein $\hat{V}^{(0)}$ is obtained by selecting, according to a pre-defined selection rule similarly applied by any and all transmitters, a predetermined set of N columns of the matrix $\hat{V}^{(0)}$ resulting from the Singular Value Decomposition operation, wherein each receiver has a quantity N of receive antennas.

[0015] Thus, a distributed block diagonal precoder is made robust to CSIT mismatch.

[0016] According to a particular feature, the overall precoder $V$ is an interference aware coordinated beamforming precoder with block-diagonal shape, $K=K_r$ and each transmitter has as a quantity M of transmit antennas equal to a quantity N of receive antennas of each receiver, each transmitter communicates only with a single receiver among the $K$ receivers such that $k=j$, wherein a sub-matrix $W_k$ such that:

$$v^{(0)}_j = E_k W_k$$

is computed as the eigenvector beamforming of the channel matrix defined by $E_k H^{(0)} E_k$ from a Singular Value Decomposition operation applied onto, said channel matrix defined by $E_k H^{(0)} E_k$ as follows:

$$E_k H^{(0)} = \mathcal{D}_k E_k$$

wherein $E_k$ is defined as follows:

$$E_k = [e_k^{(0)}, e_k^{(1)}, \ldots, e_k^{(M-1)}, \
e_k^{(M)}, \ldots, e_k^{(K)})]$$

with $e_k^{(0)}$ an $\text{M} \times (\text{k}-1) \text{M}$ sub-matrix containing only zeros, $e_k^{(j)}$ an $\text{M} \times (\text{K}-j) \text{M}$ sub-matrix containing only zeros, and $e_k^{(M)}$ an $\text{M} \times \text{M}$ identity sub-matrix.

[0017] Thus, a distributed coordinated beamforming precoder is made robust to CSIT mismatch.

[0018] According to a particular feature, refining the estimate $\hat{V}^{(0)}$ of the overall precoder $V$ is performed thanks to a refinement function $f(\ldots)$, as well as a set $\{F^{(0)}_k\}$ of refinement matrices $F^{(0)}_k, k=1$ to $K$, in an additive refinement strategy, as follows:

$$v^{(0)}_{\text{est}} = f(v^{(0)}, F^{(0)}_k v^{(0)}), k=1 \text{ to } K$$

[0019] Thus, an additive refinement allows for correcting CSIT mismatch, especially in the context of regularized zeros forcing precoders.

[0020] According to a particular feature, the overall precoder $V$ is a regularized zero-forcing precoder, and the estimate $\hat{V}^{(0)}$ of the overall precoder $V$ can be expressed as follows:

$$\hat{V}^{(0)} = \left(\mathcal{I}+\alpha \mathcal{W}^{(0)}_V\right)^{-1} \mathcal{W}^{(0)}_V$$

wherein $\alpha$ is a scalar representing a regularization coefficient that is optimized according to statistics of the own view $\mathcal{H}^{(0)}_j$ of the global MIMO channel $\mathcal{H}$ from the standpoint of said j-th transmitter, and wherein $\mathcal{W}^{(0)}$ is shared by said j-th transmitter with the other transmitters among the $K$ transmitters.

[0021] Thus, a Regularized Zero Forcing precoder is made robust to CSIT mismatch.

[0022] According to a particular feature, refining the estimate $\hat{V}^{(0)}$ of the overall precoder $V$ is performed under the following power constraint:

$$\text{Trace}\left(\mathcal{I}+\alpha \mathcal{W}^{(0)}_V \mathcal{W}^{(0)}_V\right) < N$$

wherein each receiver has a quantity N of receive antennas.

[0023] Thus, transmission power is restrained.

[0024] The present invention also concerns a device for performing transmissions of data between a plurality of $K$ transmitters and a plurality of $K$ receivers via a global MIMO channel $\mathcal{H}$, of a wireless communication system, by determining in a distributed fashion precoders to be applied for performing said transmissions, said precoders being respectively applied by said transmitters and jointly forming an overall precoder $V$, wherein said device is each and every j-th transmitter among said plurality of $K$ transmitters and comprises:

- means for gathering long-term statistics of Channel State Information at Transmitter CSIT errors incurred by each one of the k transmitters with respect to the global MIMO channel $\mathcal{H}$, the long-term statistics describing the random variation of the CSIT errors;
- means for obtaining short-term CSIT related data and building its own view $\mathcal{H}^{(0)}_j$ of the global MIMO channel $\mathcal{H}$; means for determining an estimate $\hat{V}^{(0)}$ of the overall precoder $V$ from the obtained short-term CSIT related data; means for refining the estimate $\hat{V}^{(0)}$ of the overall precoder $V$ from the standpoint of said j-th transmitter, further on the basis of its own view $\mathcal{H}^{(0)}_j$ of the global MIMO channel $\mathcal{H}$, and further on the basis of a figure of merit representative of performance of said transmissions via the global MEMO channel $\mathcal{H}$; and means for transmitting the data by applying a precoder that is formed by a part of the refined precoder $\hat{V}^{(0)}$ which relates to said j-th transmitter among said plurality of $K$ transmitters.

[0025] The present invention also concerns a computer program that can be downloaded from a communications network and/or stored on a medium that can be read by a computer or processing device. This computer program comprises instructions for causing implementation of the aforementioned method, when said program is run by a
The present invention also concerns an information storage medium, storing a computer program comprising a set of instructions causing implementation of the aforementioned method, when the stored information is read from said information storage medium and run by a processor.

Since the features and advantages related to the communications system and to the computer program are identical to those already mentioned with regard to the corresponding aforementioned method, they are not repeated here.

The characteristics of the invention will emerge more clearly from a reading of the following description of an example of embodiment, said description being produced with reference to the accompanying drawings, among which:

**V = \[ V_1, \ldots, V_K, \]**

**DESCRIPTION OF EMBODIMENTS**

**FIG. 1** schematically represents a wireless communication system 100 in which the present invention may be implemented.

The wireless communication system 100 comprises a plurality of transmitters, two 120a, 120b of which being represented in FIG. 1. The wireless communication system 100 further comprises a plurality of receivers, two 110a, 110b of which being represented in FIG. 1. For instance, the transmitters 120a, 120b are access points or base stations of a wireless telecommunications network, and the receivers 110a, 110b are mobile terminals having access to the wireless telecommunications network via said access points or base stations.

The transmitters 120a, 120b cooperate with each other in order to improve performance when performing transmissions from the plurality of transmitters 120a, 120b toward the plurality of receivers 110a, 110b via wireless links 111a, 111b, 111c, 111d. The wireless link 111a represents the transmission channel from the transmitter 120a to the receiver 110a, the wireless link 111b represents the transmission channel from the transmitter 120b to the receiver 110b, the wireless link 111c represents the transmission channel from the transmitter 120b to the receiver 110a, and the wireless link 111d represents the transmission channel from the transmitter 120b to the receiver 110b. The transmitters 120a, 120b are interconnected, as shown by a link 121 in FIG. 1A, so as to be able to exchange long-term statistics about transmission channel observations. The link 121 can be wired or wireless.

**[0035]** The cooperation is achieved by making the transmitters 120a, 120b apply respective precoders when performing said transmissions. Said precoders are determined in a distributed fashion within the wireless communication system so that each transmitter determines the precoder that said transmitter has to apply in the scope of said transmissions. More particularly, each transmitter (identified by an index j among the plurality of transmitters) determines, independently from the other transmitters of said plurality, its own view V\( j \) of an overall precoder V that should be cooperatively applied by said plurality of transmitters for performing said transmissions. This aspect is detailed hereafter with respect to FIG. 3.

**[0036]** Herein the quantity of transmitters 120a, 120b in use is denoted K\( t \), each transmitter having a quantity M of transmit antennas, and the quantity of receivers 110a, 110b in use is denoted K\( r \), each receiver having a quantity N of receive antennas. The receivers 110a, 110b are configured to simultaneously receive signals from plural transmitters among the K\( t \) transmitters. A global MIMO channel H\( t \) is thus created between the K\( t \) transmitters and the K\( r \) receivers. The part of the global MIMO channel H which links a j-th transmitter among the K\( t \) transmitters to a k-th receiver among the K\( r \) receivers is represented by an NxM matrix herein denoted H\( j,k \). One can note that H\( j,k \) is representative of a MIMO channel too. The part of the global MIMO channel H\( t \) that links the k transmitters to the k-th receiver among the K\( r \) receivers is a concatenation of the K\( r \) MIMO channels H\( j,k \) with j=1 to K\( t \), and is therefore an NxMK\( r \) matrix herein denoted H\( k \). One can further note that H\( k \) is representative of a MIMO channel too.

**[0037]** Let’s consider a set of symbol vectors \( s_j \). Each symbol vector \( s_j \) of length N represents the data that has to be transmitted to the k-th receiver among the plurality of K\( r \) receivers, at a given instant. Let’s further denote the stacked vector \( s = [s_1, s_2, \ldots, s_J]^T \) that contains all data to be transmitted by the K\( t \) transmitters to the K\( r \) receivers at said given instant, wherein A\( T \) represents the transpose of a vector or matrix A.

**[0038]** Let’s further consider the following overall precoder V:

\[ V = [V_1, \ldots, V_K] \]

and further define E\( j \)\( V \), with j=1 to K\( t \), as the part of the overall precoder V to be applied by the j-th transmitter among the K\( t \) transmitters, wherein E\( j \) is an MxNK\( r \) matrix such that E\( j \) = [0_\( \text{M} \times \text{(j-1)M} \), \( \text{I}_\text{M} \times \text{M} \), 0_\( \text{M} \times \text{(K\( t \)-j)M} \), \( \text{I}_\text{M} \times \text{M} \)]\( \text{A} \text{T} \), and wherein V\( k \) with k=1 to K\( r \), is the equivalent part of the overall precoder V which has to be applied to reach the k-th receiver among the K\( r \) receivers. Align with the notations already defined hereinbefore, one should note that V\( j \)\( k \) represents hereinafter the view of the precoder equivalent part V\( k \) from the standpoint of the j-th transmitter among the K\( t \) transmitters.

**[0039]** It should be noted that \( \text{I}_\text{M} \) in the expression of E\( j \) above represents an MxM sub-matrix of E\( j \) containing only zeros, \( \text{I}_\text{M} \times \text{M} \) represents an MxM identity matrix, \( \text{I}_\text{M} \times \text{M} \) represents an MxM sub-matrix (could be an MxM identity matrix in other contexts herein).

**[0040]** In a joint processing CoMP (Coordinated Multi-point Transmission) approach, any and all transmitters know entirely the set of the symbol vectors \( s_j \) to be transmitted toward the K\( r \) receivers at a given instant.
In a coordinated precoding approach where \( K = K_t \), each transmitter among the \( K_t \) transmitters communicates with one receiver among the \( K_r \) receivers. It means that the \( j \)-th transmitter among the \( K_t \) transmitters only has to know the symbol vector \( s_j \) to be transmitted to the \( k \)-th receiver (with \( k \neq j \)) among the \( K_r \) receivers with which said \( j \)-th transmitter communicates, which implies that the overall precoder \( V \) has a block-diagonal shape. In the case where each and every \( j \)-th transmitter among the \( K_t \) transmitters has to communicate with the \( k \)-th receiver among the \( K_r \) receivers in such a way that \( k \neq j \), reordering of the \( K_t \) transmitters with respect to the index \( j \) and/or of the \( K_r \) receivers with respect to the index \( k \) is performed so as to make the overall precoder \( V \) have a block-diagonal shape.

Considering the statements here above, a model of the wireless communication system \( 100 \) can be expressed as follows:

\[
y_k = H_k V s_k + n_k = \sum_{j=1}^{K_t} H_k k s_j + n_k
\]

wherein:

- \( y_k \) represents a symbol vector as received by the \( k \)-th receiver among the \( K_r \) receivers when the symbol vector \( s_k \) has been transmitted to said \( k \)-th receiver; and \( n_k \) represents an additive noise incurred by said \( k \)-th receiver during the transmission of the symbol vector \( s_k \).

It can be noticed that, in the formula above, the term \( H_k V s_k \) represents the useful signal from the standpoint of the \( k \)-th receiver among the \( K_r \) receivers and the sum of the terms \( H_k k s_j \) represents interference incurred by the \( k \)-th receiver among the \( K_r \) receivers during the transmission of the symbol vector \( s_j \).

A receive filter can be computed from the channel knowledge \( H_k V \) by the \( k \)-th receiver among the \( K_r \) receivers, which may be obtained by a direct estimation if pilots precoded according to the overall precoder \( V \) are sent by the concerned transmitter(s) among the \( K_t \) transmitters, or by obtaining the overall precoder \( V \) by signalling from the concerned transmitter(s) among the \( K_t \) transmitters and further by estimating the MIMO channel \( H_k \) from pilots sent without precoding on this MIMO channel \( H_k \).

When using a Zero-Forcing receive filter, the \( k \)-th receiver among the \( K_r \) receivers uses a linear filter \( T_k \) defined as follows:

\[
T_k = (H_k V)(H_k V)^{-1}
\]

When using an MMSE receive filter, the \( k \)-th receiver among the \( K_r \) receivers uses a linear filter \( T_k \) defined as follows:

\[
T_k = (H_k V)(H_k V)^{-1}
\]

Then, a decision is made by said \( k \)-th receiver on the filtered received vector \( T_k y_k \) for estimating the symbol vector \( s_k \).

It has to be noted that, in the case where there is no effective receive filter (for instance when Regularized Zero Forcing is applied by the transmitters), \( T_k = I \).

The \( K_t \) transmitters are configured to obtain CSIT (Channel State Information at the Transmitter). CSIT is obtained by each transmitter among the \( K_t \) transmitters from:

- feedback CSI (Channel State Information) from one or more receivers among the \( K_r \) receivers, and/or
- channel estimation performed at said transmitter and using a channel reciprocity property, and/or
- from such CSI or such channel estimation provided by one or more other transmitters among the \( K_t \) transmitters,
- in such a way that CSI related data and/or channel estimation related data propagation rules within the wireless communication system \( 100 \) lead to CSIT errors and moreover to CSIT mismatch among the \( K_t \) transmitters (i.e. different CSIT from the respective standpoints of the \( K_t \) transmitters), for example due to quantization operations.

One can note that, in addition to quantization operations, disparities in CSI related data effectively received by the \( K_t \) transmitters imply that differences in CSIT exist from one transmitter to another among the \( K_t \) transmitters, which leads to CSIT mismatch.

The global MIMO channel \( H \) can thus be expressed as follows, considering each and every \( j \)-th transmitter among the \( K_t \) transmitters:

\[
H = H^{(0)} + \Delta
\]

wherein \( H^{(0)} \) represents a view of the global MIMO channel \( H \) from the standpoint of the \( j \)-th transmitter among the \( K_t \) transmitters, which is obtained by said \( j \)-th transmitter from the CSIT obtained by said \( j \)-th transmitter, and wherein \( \Delta \) represents an estimate error between the effective global MIMO channel \( H \) and said view \( H^{(0)} \) of the global MIMO channel \( H \) from the standpoint of said \( j \)-th transmitter. In a similar manner, \( H_{s,j}^{(0)} \) denotes the view of the MIMO channel \( H_{s,j} \) from the standpoint of said \( j \)-th transmitter and \( f^{(0)} \) denotes the view of the MIMO channel \( H_{s,j} \) from the standpoint of said \( j \)-th transmitter.

Therefore, the view \( V^{(0)} \) of the overall precoder \( V \) might then be slightly different from one transmitter to another among the \( K_t \) transmitters, due to the CSIT mismatch. The \( j \)-th transmitter among the \( K_t \) transmitters then extracts, from the view \( V^{(0)} \) of the overall precoder \( V \) which has been determined by said \( j \)-th transmitter, the precoder \( E_j V^{(0)} \) that said transmitter has to apply in the scope of said transmissions. As already mentioned, this is independently performed by each transmitter among the \( K_t \) transmitters (\( j \) from \( 1 \) to \( K_t \)). Optimization is therefore adequately performed so as to improve the performance of the transmissions from the \( K_t \) transmitters to the \( K_r \) receivers, in spite of the CSIT mismatch and despite that each \( j \)-th transmitter among the \( K_t \) transmitters independently determines the precoder \( E_j V^{(0)} \) that said transmitter has to apply. This aspect is detailed hereafter with regard to FIG. 3.

FIG. 2 schematically represents an example of hardware architecture of a communication device, as used in the wireless communication system \( 100 \). The hardware architecture illustratively shown in FIG. 2 can represent each transmitter \( 120a \), \( 120b \) of the wireless communication system \( 100 \) and/or each receiver \( 110a \), \( 110b \) of the wireless communication system \( 100 \).

According to the shown architecture, the communication device comprises the following components interconnected by a communications bus \( 200 \): a processor, a microprocessor, a microcontroller or CPU (Central Processing Unit) \( 200 \); a RAM (Random-Access Memory) \( 201 \); a ROM (Read-Only Memory) \( 202 \); an SD (Secure Digital) card.
reader 203, or an HDD (Hard Disk Drive) or any other device adapted to read information stored on a storage medium; a first communication interface 204 and potentially a second communication interface 205.

When the communication device is one receiver among the K_p receivers, the first communication interface 204 enables the communication device to receive data from the K_p transmitters via the global MIMO channel H. The second communication interface 205 is not necessary in this case. The first communication interface 204 further enables the communication device to feed back channel state information to one or more transmitter devices among the K_p transmitters.

[0060] When the communication device is one transmitter among the K_p transmitters, the first communication interface 204 enables the communication device to transmit data to the K_p receivers, via the global MIMO channel H, cooperatively with the other transmitters among the K_p transmitters. The first communication interface 204 further enables the communication device to receive channel state information fed back by one or more receivers among the K_p receivers. Moreover, the second communication interface 205 enables the communication device to exchange data with one or more other transmitters among the K_p transmitters.

CPU 200 is capable of executing instructions loaded into RAM 201 from ROM 202 or an external memory, such as an SD card. After the communication device has been powered on, CPU 200 is capable of reading instructions from RAM 201 and executing these instructions. The instructions form one computer program that causes CPU 200 to perform some or all of the steps of the algorithm described herein.

Any and all steps of the algorithms described herein may be implemented in software by execution of a set of instructions or program by a programmable computing machine, such as a PC (Personal Computer), DSP (Digital Signal Processor) or a microcontroller; or else implemented in hardware by a machine or a dedicated component, such as an FPGA (Field-Programmable Gate Array) or an ASIC (Application-Specific Integrated Circuit).

[0063] FIG. 3 schematically represents an algorithm for determining, in a distributed fashion within the wireless communication system 100, estimations of the overall precoder V to be applied for transmitting data from the plurality of transmitters 120a, 120b toward the plurality of receivers 110a, 110b. The algorithm shown in FIG. 3 is independently performed by each transmitter among the K_p transmitters. Let’s illustratively consider that the algorithm of FIG. 3 is performed by the transmitter 120a, which is considered as the j-th transmitter among the K_p transmitters.

In a first step S301, the transmitter 120a gathers long-term statistics about the CSIT errors incurred by each one of the K_p transmitters with respect to the global MIMO channel H. The long terms statistics describe the random variation of the CSIT errors, which can for example be the variance of the CSIT errors.

[0065] By using a given statistical model of the CSIT errors, for example a centered Gaussian distribution, realizations of CSIT errors can be generated from the gathered long-term statistics for simulating the impact of said CSIT errors. Analytical derivation based on said statistical model and parameterized by said gathered long-term statistics can be performed.
with respect to the global MIMO channel $H$ (which means that all the $K$ transmitters share the same long-term statistics).

In another example said long-term statistics are gathered as disclosed in the document "A cooperative channel estimation approach for coordinated multipoint transmission networks", Qianru Li et al., IEEE International Conference on Communication Workshop (ICCW), pp. 94-99, 8-12 Jun. 2015, where a combination of channel estimates is performed between transmitter nodes in order to compute the estimation $H_{k,j}^{(g)}$ by each $j$-th transmitter among the $K$ transmitters, of the MIMO channel $H_{k,j}$, and the combination is then optimized to minimize the mean square error associated with the difference (on a per-coefficient basis) $H_{k,j}^{(g)} - H_{k,j}$ between the MIMO channel-matrices $H_{k,j}^{(g)}$ and $H_{k,j}$. The variance matrices $\Sigma_{k,j}^{(g)}$ are thus the result of the combination method described in said document.

Thus, in a particular embodiment, the transmitter $120a$ gathers the variance matrices $\Sigma_{k,j}^{(g)}$ which entries are the variance of the entries of the estimate error $\Delta_{k,j}^{(g)}$ between the effective MIMO channel $H_{k,j}$ and the estimation $H_{k,j}^{(g)}$ of the MIMO channel $H_{k,j}$ from the standpoint of the $j$-th transmitter among the $K$ transmitters.

Once the step S301 has been performed by each one of the $K$ transmitters, all the $K$ transmitters share the same long-term statistics about the CSIT errors. The step S301 is performed in an independent process than the process typically in charge of effectively configuring the $K$ transmitters so as to transmit the aforementioned set of the symbols vectors $s_k$.

It can be noted that since the aforementioned statistics about the CSIT errors are by definition long-term data, the latency for ensuring that each one of the $K$ transmitters receives said long-term statistics has low importance. Quantization is typically not a limiting factor for transmitting such long-term statistics. On the contrary, the latency for propagating data used by the $K$ transmitters so that each transmitter among the $K$ transmitters is able to build its own CSIT is of most importance, in order for the wireless communication system 100 to have good reactivity. Quantization with few levels can then be necessary for transmitting such CSIT related data and can drastically reduce the quality of the information. By the way, confusion shall be avoided between long-term statistics about CSIT errors received by the transmitter $120a$ in the step S301 and CSIT related data needed by the transmitter $120a$ to have its own view $\hat{H}^{(g)}$ of the global MIMO channel $H$.

In a step S302, the transmitter $120a$ obtains up-to-date (i.e. short-term) CSIT related data needed by the transmitter $120a$ to have its own view $\hat{H}^{(g)}$ of the global MIMO channel $H$. The transmitter $120a$ preferably shares the CSIT obtained in the step S302 with one or more transmitters among the $K$ transmitters, in order to help said one or more transmitters to build their own respective view of the global MIMO channel $H$.

Once the step S302 is performed by all the $K$ transmitters independently (substantially in parallel), the CSIT finally obtained by the $K$ transmitters differs from one transmitter to another one among the $K$ transmitters, which leads to CSIT mismatch.

In a step S303, the transmitter $120a$ determines an initial version $\hat{V}^{(g)}$ from the standpoint of the transmitter $120a$ (considered as the $j$-th transmitter among the $K$ transmitters), of the overall precoder $V$ from the CSIT related data obtained by the transmitter $120a$ in the step S302. The initial version $\hat{V}^{(g)}$ of the overall precoder $V$ is then an estimate of the overall precoder $V$. Since there is CSIT mismatch, this initial version $\hat{V}^{(g)}$ of the overall precoder $V$ may involve residual interference that grows with the CSIT mismatch.

In a particular embodiment, the type of the overall precoder $V$ and thus of the estimate $\hat{V}^{(g)}$ of the overall precoder $V$ are both of one precoder type among the followings:

- block-diagonalization precoders, for coordinated multi-point transmissions with joint processing, as addressed in the document “Cooperative Multi-Cell Block Diagonalization with Per-Base-Station Power Constraints”, Rui Zhang, in IEEE Journal on Selected Areas in Communications, vol. 28, no. 9, pp. 1435-1445, December 2010;
- interference aware coordinated beamforming precoders, for coordinated multi-point transmissions with coordinated precoding, as addressed in the document “Interference Aware-Coordinated Beamforming in a Multi-Cell System”, Chan-Byoung Chae et al., in IEEE Transactions on Wireless Communications, vol. 11, no. 10, pp. 3692-3703, October 2012; and
- regularized zero-forcing precoders, for coordinated multi-point transmissions with joint processing, as addressed in the document “A large scale analysis of cooperative multicell downlink system with imperfect CSIT”, Jun Zhang et al., in IEEE International Conference on Communications (ICC), pp. 4813-4817, 10-15 Jun. 2012.

A particular embodiment of the present invention for each one of these types of precoders is detailed hereafter.

It has to be noted that the initial version $\hat{V}^{(g)}$ of the overall precoder $V$ from the CSIT related data obtained by the transmitter $120a$ (considered as the $j$-th transmitter among the $K$ transmitters) can be determined as indicated in the documents referenced above with respect to each precoder type.

In a step S304, the transmitter $120a$ refines the initial version $\hat{V}^{(g)}$ of the overall precoder $V$ according to the CSI error long-term statistics obtained in the step S301, so as to obtain a refined precoder $V^{(r)} = \{V^{r}_{1}, V^{r}_{2}, \ldots, V^{r}_{K}\}$, which is the view of the overall precoder $V$ from the standpoint of the transmitter $120a$ (considered as the $j$-th transmitter among the $K$ transmitters).

In a particular embodiment, refining the initial version $\hat{V}^{(g)}$ of the overall precoder $V$ is performed by the transmitter $120a$ thanks to a refinement function $f(\cdot, \cdot)$, as well as a set $\{V^{r} \}$ of refinement matrices $V^{r}_{j}$, $j$ to $K$. More particularly, considering that $\hat{V}^{(g)} = \{\hat{V}^{(g)}_{1}, \ldots, \hat{V}^{(g)}_{K}\}$, refining the initial version $\hat{V}^{(g)}$ of the overall precoder $V$ means refining the sub-matrices $\hat{V}^{(g)}_{j}$, $j$ to $K$, of the initial version $\hat{V}^{(g)}$ of the overall precoder $V$, wherein each sub-matrix $\hat{V}^{(g)}_{j}$ is the equivalent within $\hat{V}^{(g)}$ of the sub-matrix $V^{r}_{j}$ within $V^{(r)}$.

Therefore, for each sub-matrix $\hat{V}^{(g)}_{j}$, the refinement function $f(\cdot, \cdot)$ and the refinement matrix $V^{r}_{j}$ can be applied in a multiplicative refinement strategy, such as:

\[ V^{(r)}_{j} = f(\hat{V}^{(g)}_{j}, V^{r}_{j}) = \hat{V}^{(g)}_{j} V^{r}_{j} \]

or in an additive refinement strategy:

\[ V^{(r)}_{j} = f(\hat{V}^{(g)}_{j}, V^{r}_{j}) = V^{r}_{j} + \hat{V}^{(g)}_{j} \]
preference under the following power constraint:
\[
\text{Trace}(f^T(\mathbf{P})f^T(\mathbf{V})) = \mathbf{N}
\]

[0084] It has to be noticed from the relationships above that the size of each refinement matrix \( F_{j}^{(\mathbf{V})} \) depends on whether the refinement strategy is additive or multiplicative.

[0085] Refining the initial version \( \mathbf{V}^{(0)} \) of the overall precoder \( \mathbf{V} \) is further performed as a function of the view \( \mathbf{H}^{(j)} \) of the global MIMO channel \( \mathbf{H} \) from the standpoint of the transmitter \( 120a \) (considered as the \( j \)-th transmitter among the \( K \) transmitters), as well as of a figure of merit representative of performance of transmissions from the transmitters to the receivers via the global MIMO channel \( \mathbf{H} \), so as to be able to determine optimized version of the set \{ \( F_{k}^{(\mathbf{V})} \) \} of the refinement matrices \( F_{k}^{(\mathbf{V})} \), \( k = 1 \) to \( K \). In such a wireless communication system, the figure of merit that is representative of performance of the transmissions via the global MIMO channel \( \mathbf{H} \) is typically a multi-user performance metric.

[0086] It has to be noted that the precoder \( \mathbf{V}^{(0)} \) being a refined version of the initial version \( \mathbf{V}^{(0)} \) of the overall precoder \( \mathbf{V} \) from the standpoint of each \( j \)-th transmitter among the \( K \) transmitters computed from its own view \( \mathbf{H}^{(j)} \) of the global MIMO channel \( \mathbf{H} \), a mismatch exists between the precoders \( \mathbf{V}^{(0)} \) independently computed by all the \( K \) transmitters. Thus, a refinement operation should be designed so as to minimize the impact of the mismatch on the performance characterized by the figure of merit. It can be noticed that the transmitters have two types of information for designing the precoder \( \mathbf{V}^{(0)} \) : first, the local CSI, which is represented by the view \( \mathbf{H}^{(j)} \) of the global MIMO channel \( \mathbf{H} \) from the standpoint of each \( j \)-th transmitter, and which is exploited to compute the initial version \( \mathbf{V}^{(0)} \) of the overall precoder \( \mathbf{V} \), and the long term statistics on estimate error between the effective global MIMO channel \( \mathbf{H} \) and said view \( \mathbf{H}^{(j)} \), which are shared between all transmitters and can thus be exploited for said refinement operation. Since a statistics-based refinement is considered, the refinement operation is a statistical method that computes a refined precoder \( \mathbf{V}^{(0)} \) out of a set of intermediate random variable \( \mathbf{V}^{(0)} \) characterizing the possible overall precoder \( \mathbf{V} \) in view of the previously determined initial version \( \mathbf{V}^{(0)} \) of the overall precoder \( \mathbf{V} \) and of the long term statistics on estimate error between the effective global MIMO channel \( \mathbf{H} \) and said view \( \mathbf{H}^{(j)} \) for each \( j \)-th transmitter. Furthermore, the refinement strategy (multiplicative or additive) can be defined in order to be able to statistically correct the initial version \( \mathbf{V}^{(0)} \) into \( \mathbf{V}^{(0)} \), thus refinement strategy involving parameters to be optimized so as to statistically reduce the impact of the mismatch on the performance.

[0087] Thus, each \( j \)-th transmitter can compute the distribution of an intermediate random variable \( \mathbf{V}^{(0)} \) (as defined hereafter), or generate realizations thereof, associated with the overall precoder \( \mathbf{V} \) after refinement by all the transmitters, according to the refinement strategy (multiplicative or additive) in use and to the gathered long-term statistics about the CSI errors, further according to the initial version \( \mathbf{V}^{(0)} \) of the overall precoder \( \mathbf{V} \) from the standpoint of said \( j \)-th transmitter and of its own view \( \mathbf{H}^{(j)} \) of the global MIMO channel \( \mathbf{H} \), as detailed hereafter.

[0088] In a first particular embodiment, the figure of merit is a lower bound of a sum rate \( \text{LBSR}^{(j)} \) reached via the global MIMO channel \( \mathbf{H} \), from the standpoint of the transmitter \( 120a \) (considered as the \( j \)-th transmitter among the \( K \) transmitters), with respect to its own view \( \mathbf{H}^{(j)} \) of the global MIMO channel \( \mathbf{H} \). The sum rate lower bound \( \text{LBSR}^{(j)} \) is a function of the set \{ \( F_{k}^{(\mathbf{V})} \) \}. Considering that the transmitter \( 120a \) views the global MIMO channel \( \mathbf{H} \) as being \( \mathbf{H}^{(j)} \), the sum rate lower bound \( \text{LBSR}^{(j)} \) is then defined as follows:

\[
\text{LBSR}^{(j)} = \sum_{k=1}^{K} \log(\det(\text{MSE}_{k}^{(\mathbf{V})(F_{k}^{(\mathbf{V})}, \ldots, F_{j}^{(\mathbf{V})})}))
\]

where
\[
\text{MSE}_{k}^{(\mathbf{V})(F_{k}^{(\mathbf{V})}, \ldots, F_{j}^{(\mathbf{V})})} = \text{E}_{[\{0, \ldots, 2^{\mathbf{M}}\}]}[\text{EMSE}_{k}^{(\mathbf{V})(F_{k}^{(\mathbf{V}), \ldots, F_{j}^{(\mathbf{V})})}]^{1/2}]
\]

wherein \( \text{E} \) represents the mathematical expectation and, wherein \( \text{EMSE}_{k}^{(\mathbf{V})(F_{k}^{(\mathbf{V})}, \ldots, F_{j}^{(\mathbf{V})})} \) represents the mean square error matrix between the symbol vector \( s_{k} \) and the corresponding filtered received vector \( \mathbf{r}_{k, j} \) (as already explained) for a realization of the estimate errors \( \mathbf{e}_{k, j}^{(1)}, \mathbf{e}_{k, j}^{(2)}, \ldots, \mathbf{e}_{k, j}^{(K)} \) which matches the long terms statistics of CSI errors as obtained in the step \( S301 \), for example by considering a centred Gaussian distribution of the CSI errors, and for the view \( \mathbf{H}^{(j)} \) of the global MIMO channel \( \mathbf{H} \) from the standpoint of the transmitter \( 120a \). As explained in more details hereafter, computing \( \text{MSE}_{k}^{(\mathbf{V})} \) for all and any \( k \)-th receiver among the \( K \) transmitters would allow each considered \( j \)-th transmitter among the \( K \) transmitters to perform the optimization of the considered figure of merit. However, the effective realization of the estimate errors \( \mathbf{e}_{k, j}^{(1)}, \mathbf{e}_{k, j}^{(2)}, \ldots, \mathbf{e}_{k, j}^{(K)} \) is unknown. An approximation is therefore performed by relying on \( \text{EMSE}_{k}^{(\mathbf{V})} \) instead of \( \text{MSE}_{k}^{(\mathbf{V})} \) thanks to the use of the long-term statistics about the CSI errors, which have been gathered in the step \( S301 \).

[0089] The receiver filter \( \mathbf{T}_{k} \) may be a function of the overall precoder \( \mathbf{V} \) and of the global MIMO channel \( \mathbf{H} \), which are unknown at the transmitters. But, each \( j \)-th transmitter can instead rely on its own view \( \mathbf{H}^{(j)} \) of the global MIMO channel \( \mathbf{H} \) and realizations of the estimate errors \( \mathbf{e}_{k, j}^{(1)}, \mathbf{e}_{k, j}^{(2)}, \ldots, \mathbf{e}_{k, j}^{(K)} \) matching the long-term statistics gathered in the step \( S301 \), so as to obtain the intermediate random variable \( \mathbf{V}^{(j)} \) and to obtain its own view \( \mathbf{H}^{(j)} \) of each receive filter \( \mathbf{T}_{k} \), \( k = 1 \) to \( K \), as described hereafter. As a remark, the intermediate random variable \( \mathbf{V}^{(j)} \) and the view \( \mathbf{H}^{(j)} \) of the receive filter \( \mathbf{T}_{k} \) are functions of the set \{ the refinement matrices \( F_{k}^{(\mathbf{V})} \), \( k = 1 \) to \( K \).

[0090] Since \( \text{EMSE}_{k}^{(\mathbf{V})(F_{k}^{(\mathbf{V})}, \ldots, F_{K}^{(\mathbf{V})})} \) may be computed for a fixed set of parameters \( F_{1}^{(\mathbf{V})}, \ldots, F_{K}^{(\mathbf{V})} \), the sum rate lower bound \( \text{LBSR}^{(j)} \) may be optimized by randomly defining several candidate sets of matrices to form the set \{ \( F_{k}^{(\mathbf{V})} \) \} of the refinement matrices \( F_{k}^{(\mathbf{V})} \), \( k = 1 \) to \( K \), and keeping the candidate set that minimizes the sum rate lower bound \( \text{LBSR}^{(j)} \) from the standpoint of the transmitter \( 120a \).

[0091] In a preferred embodiment, an optimized sum rate lower bound \( \text{LBSR}^{(j)} \) is obtained thanks to an iterative algorithm as detailed hereafter with regard to FIG. 4.

[0092] In a second particular embodiment, the figure of merit is the sum of traces, for \( k = 1 \) to \( K \), of \( \text{EMSE}_{k}^{(\mathbf{V})(F_{1}^{(\mathbf{V})}, \ldots, F_{K}^{(\mathbf{V})})} \) as follows, which leads to a simplified expression \( \text{MINMSE}^{(j)} \) thus involving simpler implementation:
The algorithm of FIG. 3 may be applied independently by all the transmitters on a regular basis. The algorithm of FIG. 3 may be applied independently by all the transmitters upon detecting that the global MIMO channel $H$ has changed beyond a predefined threshold. The algorithm of FIG. 3 may be applied independently by all the transmitters before each transmission of data from the $K$ transmitters toward the $K$ receivers.

Particular embodiment for block-diagonalization precoders

In this particular embodiment, the overall precoder $V$ is a block-diagonalization precoder. It is then assumed that $K,M,K,N$. By definition of block-diagonalization, considering the $k$th receiver among the $K$ receivers, the interference induced by the MIMO channels for all other receivers among the $K$ receivers is supposed to be eliminated, which means that, ideally:

$$h_{lk} v_{l} \rho_{k} = 0$$

Let’s denote $H_{lk}$ an aggregated interference channel for the $k$th receiver among the $K$ receivers, which is expressed as follows:

$$h_{lk} = [h_{l1},\ldots,h_{lk},\ldots,h_{lN},\ldots,h_{lK}]$$

and similarly $h_{lk}$ an aggregated interference channel estimation for the $k$th receiver among the $K$ receivers, which is expressed as follows:

$$\hat{h}_{lk} = [h_{l1},\ldots,h_{lk},\ldots,h_{lN},\ldots,h_{lK}]$$

Applying a Singular Value Decomposition (SVD) operation on the expression above of the aggregated interference channel $H_{lk}$ results in:

$$\hat{h}_{lk} = u_{lk} d_{lk} v_{lk}^\top$$

wherein:

$U_{lk}$ is an $(N,K-1)\times(N,K-1)$ unitary matrix,
$D_{lk}$ is an $(N,K-1)\times(N,K-1)$ diagonal matrix,
$V_{lk}$ is an $(M,K)\times(N,K-1)$ matrix, and
$V_{lk}^\top$ is an $(M,K)\times(N,K-1)$ matrix.

The size of the part $V_{lk}$ of the overall precoder $V$ which has to be applied for transmitting data toward the $k$th receiver is $K\times N$, and $V_{lk}$ is obtained by selecting a predetermined set of $N$ columns of the matrix $V_{lk}$. The predetermined set can either be, according to a predefined selection rule, the $N$ first columns of $V_{lk}$ or the $N$ last columns of $V_{lk}$.

Considering the view $H(\theta)$ of the global MIMO channel $H$ from the standpoint of the jth receiver among the $K$ transmitters, the expression above becomes:

$$\hat{H}(\theta) = \hat{U}(\theta) D(\theta) v(\theta)^\top$$

wherein $\hat{H}(\theta)$ represents the view of the aggregated interference channel estimation $\hat{H}_{lk}$ for the $k$th receiver among the $K$ receivers from the standpoint of the jth transmitter among the $K$ transmitters, wherein $V_{lk}(\theta)$ is an $MK\times N(K-1)$ matrix equivalent to $V_{lk}$ when using the estimation $H(\theta)$ instead of the effective MIMO channel $H$ and $V_{lk}(\theta)$ is an $MK\times M(K-1)$ matrix equivalent to $V_{lk}$ when using the estimation $H(\theta)$ instead of the effective MIMO channel $H$, and wherein $V_{lk}(\theta)$ is obtained by selecting a predetermined set of $N$ columns of the matrix $V_{lk}(\theta)$ according to the predefined selection rule, the selection rule being similarly applied by any and all transmitters, and wherein $V_{lk}(\theta)$ is such that the refinement function $f(\theta,\ldots)$ used in the aforementioned multiplicative refinement strategy, which means:

$$V_{lk}(\theta) = V_{lk}(\theta)^{\rho_{k}}$$

where $F_{\rho_{k}}$ is a $N\times N$ matrix, preferably under the following constraint:

$$\text{trace}(F_{\rho_{k}}) < N$$

As a result of the precoding strategy, the block-diagonalization property is conserved, which means:

$$H_{lk} V_{lk}(\theta) = 0, \forall k$$

However, it has to be noted that the block-diagonalization property is usually not achieved during the transmission on the global MIMO channel $H$, since a mismatch exists between $H(\theta)$ and $H$. Thus, if the transmitters use their initial version $\hat{H}(\theta)$ of the precoder for performing the transmissions, interference exists between the transmissions towards the receivers. This interference can be reduced by using the statistical knowledge on the long term statistics on estimate error between the effective global MIMO channel $H$ and said view $H(\theta)$, by using the appropriate (multiplicative or additive) refinement strategy.

Therefore, by applying an SVD operation on the view $H(\theta)$ of the global MIMO channel $H$ from the standpoint of the transmitter $120a$ (considered as the jth transmitter among the $K$ transmitters), the matrices $V_{lk}(\theta)$ and $V_{lk}(\theta)$ can be determined by the transmitter $120a$ (considered as the jth transmitter among the $K$ transmitters).

Refining the initial version $\hat{V}(\theta)$ of the overall precoder $V$ thus consists in optimizing the set of $\{F_{\rho_{k}}(\theta)\}$ of the refinement matrices $F_{\rho_{k}}(\theta)$ with respect to the set of $\hat{V}(\theta)$ of the matrices $\hat{V}(\theta)$ obtained by the application of the Singular Value Decomposition on the view $H(\theta)$ of the global MIMO channel $H$ from the standpoint of the transmitter $120a$ (considered as the jth transmitter among the $K$ transmitters).

First, a system performance metric is derived for a fixed realization of the estimate errors $\Delta^{(1)},\Delta^{(2)},\ldots,\Delta^{(K)}$ known by the transmitters, and then a statistical analysis on the estimate errors $\Delta^{(1)},\Delta^{(2)},\ldots,\Delta^{(K)}$, which are random variables, is applied according to their respective long term statistics gathered at the step $\text{S301}$.

Considering that an MMSE filter is implemented at each one of the $K$ receivers for filtering signals received
from the \( K \) transmitters, the expression of the MMSE filter, as computed at the \( k \)-th receiver from the perspective of the \( j \)-th transmitter and for a fixed realization of the estimate errors \( \Delta^{(1)}, \Delta^{(2)}, \ldots, \Delta^{(K)} \) is:

\[
\mathbf{T}_k^{(j)} = (\mathbf{H}_k^{(j)})^\dagger \left[ \sum_{i=1}^{K} (\mathbf{H}_i^{(j)})^\dagger (\mathbf{V}_i^{(j)}) (\mathbf{H}_i^{(j)})^\dagger \mathbf{H}_i^{(j)} + \mathbf{A}_i^{(j)} \right]^{-1}
\]

wherein \( \tilde{\mathbf{V}}_k^{(j)} \) is the part of the intermediate random variable \( \mathbf{V}_k^{(j)} \) which concerns the \( k \)-th receiver among the \( K \) receivers, by taking into account that the other transmitters among the \( K \) transmitters also have performed a refinement according to a fixed realization of the estimate errors \( \Delta^{(1)}, \Delta^{(2)}, \ldots, \Delta^{(K)} \).

[0111] Therefore, each \( j \)-th transmitter among the \( K \) transmitters computes the following, for each and every \( \ell \)-th receiver among the \( K \), \( \ell = 1 \) to \( K \):

\[
\Psi_\ell^{(j)} = \begin{bmatrix}
E_1^{(j)} (\mathbf{V}_1^{(j)} + (\mathbf{H}_1^{(j)})^\dagger (\mathbf{H}_1^{(j)}) \mathbf{A}_1^{(j)} \mathbf{V}_1^{(j)})
E_2^{(j)} (\mathbf{V}_2^{(j)} + (\mathbf{H}_2^{(j)})^\dagger (\mathbf{H}_2^{(j)}) \mathbf{A}_2^{(j)} \mathbf{V}_2^{(j)})
\vdots
E_K^{(j)} (\mathbf{V}_K^{(j)} + (\mathbf{H}_K^{(j)})^\dagger (\mathbf{H}_K^{(j)}) \mathbf{A}_K^{(j)} \mathbf{V}_K^{(j)})
\end{bmatrix}
\]

and wherein \( \mathbf{A}^{(j)} \) represents the error estimation for the considered \( \ell \)-th receiver from the standpoint of the considered \( j \)-th transmitter, and

\[
\mathbf{A}^{(j)} = \begin{bmatrix}
\Delta^{(1)} \\
\Delta^{(2)} \\
\vdots \\
\Delta^{(K)}
\end{bmatrix}
\]

and \( \mathbf{H}_k^{(j)} \) represents the view of the MIMO channel \( \mathbf{H}_k \) from the standpoint of the considered \( j \)-th transmitter, and \( \mathbf{H}_k^{(j)} \) represents an estimation of the aggregated interference channel \( \mathbf{H}_k \) for the considered \( \ell \)-th receiver from the standpoint of the considered \( j \)-th transmitter.

[0112] Indeed, it is reminded that:

\[
\mathbf{H}_k^{(j)} = \mathbf{H}_k^{(j)} + \mathbf{A}^{(j)}
\]

which then means that, when a fixed realization of the estimate errors \( \Delta^{(1)}, \Delta^{(2)}, \ldots, \Delta^{(K)} \) is known by the considered \( j \)-th transmitter, said \( j \)-th transmitter can compute the view \( \mathbf{H}_k^{(j)} \) of the global MIMO channel \( \mathbf{H}_k \) from the standpoint of any other \( j \)-th transmitter among the \( K \) transmitters as follows:

\[
\mathbf{H}_k^{(j)} = \mathbf{H}_k^{(j)} + \mathbf{A}^{(j)}
\]

[0113] Thus computing \( \Psi_\ell^{(j)} \), \( \ell = 1 \) to \( K \), as expressed above, allows then computing \( \mathbf{T}_k^{(j)} \), which then allows defining \( \text{EMSE}_k^{(j)} \) as follows:

\[
\text{EMSE}_k^{(j)} = \mathbf{E}_{\mathbf{w}_k} \left[ (\mathbf{y}_k - \mathbf{H}_k^{(j)} \mathbf{x}_k)^\dagger (\mathbf{y}_k - \mathbf{H}_k^{(j)} \mathbf{x}_k) \right]
\]

wherein \( \mathbf{I} \) is an identity matrix.

[0114] Since the effective fixed realization of the estimate errors \( \Delta^{(1)}, \Delta^{(2)}, \ldots, \Delta^{(K)} \) is unknown at the transmitters in practice, but since the estimate errors \( \Delta^{(1)}, \Delta^{(2)}, \ldots, \Delta^{(K)} \) are associated with a given probability of occurrence that can be computed from the long term statistics on CSI error gathered in the step S301, a statistical analysis can be used.

[0115] Each \( j \)-th transmitter (such as the transmitter 120a) is then able to compute \( \text{EMSE}_k^{(j)}(\mathbf{F}_k^{(j)}, \ldots, \mathbf{F}_k^{(j)}) \) by using a Monte Carlo simulation, or by using a numerical integration, on the distribution of \( \Delta^{(1)}, \Delta^{(2)}, \ldots, \Delta^{(K)} \) in view of the long term statistics on CSI error gathered in the step S301, further with respect to the view \( \mathbf{H}_k^{(j)} \) of the global MIMO channel \( \mathbf{H}_k \) from the standpoint of the transmitter 120a (considered as the \( j \)-th transmitter among the \( K \) transmitters).

[0116] Alternatively a mathematical approximation provides a closed form expression of \( \text{EMSE}_k^{(j)}(\mathbf{F}_k^{(j)}, \ldots, \mathbf{F}_k^{(j)}) \), as follows:

\[
\text{EMSE}_k^{(j)} = \left( \sum_{i=1}^{K} \mathbf{H}_k^{(j)} (\mathbf{F}_k^{(j)}) (\mathbf{F}_k^{(j)})^\dagger \right) + \left( \sum_{i=1}^{K} \mathbf{H}_k^{(j)} (\mathbf{F}_k^{(j)}) (\mathbf{F}_k^{(j)})^\dagger \right) + \left( \sum_{i=1}^{K} \mathbf{H}_k^{(j)} (\mathbf{F}_k^{(j)}) (\mathbf{F}_k^{(j)})^\dagger \right)
\]

wherein

\[
\mathbf{H}_k^{(j)} = \mathbf{H}_k^{(j)} + \mathbf{A}^{(j)}
\]

and wherein \( \mathbf{A}^{(j)} \) is the Moore-Penrose pseudo-inverse of \( A \), \( \text{diag}(.) \) makes a diagonal matrix from a given vector and \( \text{diag}(.) \) retrieves the diagonal entries of a matrix and stacks them into a vector.

[0117] Therefore, optimization of a figure of merit being a function of \( \text{EMSE}_k^{(j)} \), such as the sum rate lower bound
LBSRM or the simplified expression MINMSE\(^{ij}\), according to the mathematical expectation of the realization of the estimate errors \(\Delta^{(1)}, \Delta^{(2)}, \ldots, \Delta^{(K)}\), which matches the long-term statistics of CSIT error as obtained in the step S301, leads to obtaining the appropriate set \(\{F_{k}^{(i)}\}\) of the refinement matrices \(F_{k}^{(i)}, k=1 \rightarrow K_{r}\), and then to obtaining the refined precoder \(\tilde{V}_{k}^{(i)}\) from said appropriate set \(\{F_{k}^{(i)}\}\) of the refinement matrices \(F_{k}^{(i)}\) by applying the aforementioned multiplicative refinement strategy.

[0118] In a preferred embodiment, an optimized sum rate lower bound LBSRU) is obtained thanks to the iterative algorithm as detailed hereafter with regard to FIG. 4.

[0119] Particular embodiment for interference aware coordinated beamforming precoders

[0120] In this particular embodiment, it is assumed that the quantity \(K_{r}\) of transmitters is equal to the quantity \(K_{r}\) of receivers, i.e. \(K_{r}=K_{r}\), and that the quantity \(M\) of transmit antennas is equal to the quantity \(N\) of receive antennas, i.e. \(M=N\). Moreover each one of the \(K_{r}\) transmitters communicates only with a single receiver among the \(K_{r}\) receivers. Considering any k-th transmitter among the \(K_{r}\) transmitters, the j-th transmitter among the \(K_{r}\) transmitters which communicates with said k-th receiver is such that \(k=j\). In the mathematical expressions used hereafter in the particular embodiment for interference aware coordinated beamforming precoders, the index \(j\) is not used hereinbefore for identifying any receiver among the \(K_{r}\) receivers) can be used instead of the index \(j\). Interference aware coordinated beamforming precoding is a sub-case of the block-diagonalization precoding detailed above. Indeed, by considering that the overall precoder \(\tilde{V}\) has a block diagonal structure, with \(K_{t}\) blocks of size \(M\), it is considered that each and every k-th transmitter among the \(K_{r}\) transmitters only knows the symbol vector \(s_{k}\) (and not the other symbol vectors \(s_{j}, 1 \leq j \leq K_{r}\)) that have to be transmitted by the other transmitters among the \(K_{r}\) transmitters), which is precoded by an \(M\times M\) sub-matrix \(W_{k}\) such that:

\[
\tilde{V}_{k}=E_{k}W_{k}
\]

[0121] The sub-matrices \(W_{k}\), for \(k=1 \rightarrow K_{r}\), are obtained by implementing beamforming and/or interference alignment based on the view \(\tilde{H}_{k}^{(i)}\) of the global MIMO channel \(H\) from the standpoint of each k-th transmitter. For example, the sub-matrices \(W_{k}\) are computed according to an interference alignment technique, as in the document “Downlink Interference Alignment” Changho Suh et al, IEEE Transactions on Communications, vol. 59, no. 9, pp. 2616-2626, September 2011. In another example, the sub-matrices \(W_{k}\) are computed as the eigenvector beamforming of the channel matrix defined by \(E_{k}^{(i)}\tilde{H}_{k}^{(i)}E_{k}\), from an SVD operation applied onto said channel matrix by the considered k-th transmitter among the \(K_{r}\) transmitters, such that:

\[
E_{k}^{(i)}\tilde{H}_{k}^{(i)}E_{k}=U_{k}D_{k}W_{k}
\]

wherein:

[0122] \(U_{k}\) is an \(NK_{r}\times NK_{r}\), unitary matrix, and

[0123] \(D_{k}\) is an \(NK_{r}\times NK_{r}\), diagonal matrix.

[0124] The optimization is then very similar to the approach described above with respect to the block-diagonalization precoding.

[0125] Then, the approach described above with respect to the block-diagonalization precoding can thus be similarly applied, as follows.

[0126] First, an initial version \(\tilde{V}_{k}^{(i)}\) of the overall precoder \(\tilde{V}\) from the standpoint of each j-th transmitter among the \(K_{r}\) transmitters is computed from its own view \(\tilde{H}_{k}^{(i)}\) of the global MIMO channel \(H\), such that the overall precoder \(\tilde{V}\) and the initial version \(\tilde{V}_{k}^{(i)}\) thereof have a block diagonal structure. Each block defined by \(E_{k}^{(i)}\tilde{V}_{k}^{(i)}E_{k}\) is related to the precoder used at the k-th transmitter from the standpoint of each j-th transmitter, only for preceding the symbols vector \(s_{k}\), and is related to the sub-matrix \(W_{k}\) previously described and determined according to an interference alignment or an the eigenvector beamforming technique.

[0127] The initial version \(\tilde{V}_{k}^{(i)}\) is such that the refinement function \(f(\cdot, \cdot)\) is used in the aforementioned multiplicative refinement strategy, which means:

\[
\tilde{V}_{k}^{(i)}=\tilde{V}_{k}^{(i)}W_{k}^{(i)}F_{k}^{(i)}
\]

where \(F_{k}^{(i)}\) is a \(N\times N\) matrix, preferably under the following constraint:

\[
\text{Trace}(F_{k}^{(i)}F_{k}^{(i)})=N
\]

[0128] Each j-th transmitter (such as the transmitter 120a) is then able to compute EMSE\(^{ij}\)(\(F_{k}^{(i)}, \ldots, F_{k}^{(i)}\)) by using a Monte Carlo simulation, or by using a numerical integration, on the distribution of \(\Delta^{(1)}, \Delta^{(2)}, \ldots, \Delta^{(K)}\) which matches the long-term statistics of CSIT error as obtained in the step S301, further with respect to the view \(\tilde{H}_{k}^{(i)}\) of the global MIMO channel \(H\) from the standpoint of the transmitter 120a (considered as the j-th transmitter among the \(K_{r}\) transmitters), under the constraint that the refinement matrices \(F_{k}^{(i)}\) show block-diagonal respective shapes, by using:

\[
\text{EMSE}_{k}^{ij}(F_{k}^{(i)}, \ldots, F_{k}^{(i)}) = \mathbb{E}(f(k)(F_{k}^{(i)}F_{k}^{(i)^{\dagger}})) = \underbrace{\mathbb{E}(f(k)(F_{k}^{(i)}F_{k}^{(i)^{\dagger}}))}_{k=1} + \underbrace{\mathbb{E}(f(k)(F_{k}^{(i)}F_{k}^{(i)^{\dagger}}))}_{k=j}
\]

[0129] Alternatively a mathematical approximation provides a closed form expression of EMSE\(^{ij}\)(\(F_{k}^{(i)}, \ldots, F_{k}^{(i)}\), as follows:

\[
\text{EMSE}_{k}^{ij}(F_{k}^{(i)}, \ldots, F_{k}^{(i)}) = \mathbb{E}(f(k)(F_{k}^{(i)}F_{k}^{(i)^{\dagger}})) = \underbrace{\mathbb{E}(f(k)(F_{k}^{(i)}F_{k}^{(i)^{\dagger}}))}_{k=1} + \underbrace{\mathbb{E}(f(k)(F_{k}^{(i)}F_{k}^{(i)^{\dagger}}))}_{k=j}
\]

wherein:

\[
\Phi_{k} = \sum_{k=1}^{K_{r}} H_{k}^{(i)}E_{k}^{(i)}E_{k}^{(i)^{\dagger}}
\]

[0122] \(U_{k}\) is an \(NK_{r}\times NK_{r}\), unitary matrix, and

[0123] \(D_{k}\) is an \(NK_{r}\times NK_{r}\), diagonal matrix.
wherein $\mathbf{F}_k^{(i)}$ is a $\mathcal{M}_K \times \mathcal{N}$ matrix.

[0134] First, a system performance metric is derived for a fixed realization of the estimate errors $\Delta^{(1)}$, $\Delta^{(2)}$, ..., $\Delta^{(K)}$ known by the transmitters, and then a statistical analysis on the estimate errors $\Delta^{(1)}$, $\Delta^{(2)}$, ..., $\Delta^{(K)}$, which are random variables, is applied according to their respective long term statistics gathered at the step S301.

[0135] $\mathbf{V}^{(i)}$ can be computed for a fixed realization of $\Delta^{(1)}$, $\Delta^{(2)}$, ..., $\Delta^{(K)}$, and with respect to the view $\mathbf{H}^{(o)}$ of the global MIMO channel $\mathbf{H}$ from the standpoint of the transmitter 120a (considered as the j-th transmitter among the $K$ transmitters), as follows:

$$
\mathbf{V}^{(i)} = \mathbf{F}_k^{(i)} \mathbf{R}_k^{(i)} \mathbf{F}_k^{(i) H}
$$

wherein $\text{Re}\{X\}$ represents the real part of the complex input $X$.

and wherein $\text{Cov}^{-1}(\mathbf{P}_k^{(i) H}\mathbf{P}_k^{(i) o\alpha})^{-1}$ which matches the long-term statistics of CSIT error as obtained in the step S301, leads to obtaining the appropriate set $\{\mathbf{E}_k^{(i)}\}$ of the refinement matrices $\mathbf{F}_k^{(i) o\alpha}$, $\mathbf{F}_k^{(i)}$ to $\mathbf{K}$, and then to obtaining the refined precoder $\mathbf{V}^{(i)}$ from said appropriate set $\{\mathbf{E}_k^{(i)}\}$ of the refinement matrices $\mathbf{F}_k^{(i)}$ by applying the aforementioned multiplicative refinement strategy.

[0131] In a preferred embodiment, an optimized sum rate lower bound LBSRW is obtained thanks to the iterative algorithm detailed hereafter with regard to FIG. 4.

[0132] Particular embodiment for regularized zero-forcing precoders

[0133] In this particular embodiment, the estimate $\hat{\mathbf{V}}^{(i)}$ of the overall precoder $\mathbf{V}$ from the standpoint of each and every j-th transmitter among the $K$ transmitters can be expressed as follows, with respect to each and every k-th receiver among the $K$ receivers:

$$
\hat{\mathbf{V}}^{(i)} = \alpha^{(i)} \mathbf{H}^{(o)} \mathbf{P}_k^{(i) o\alpha} \mathbf{H}^{(i) H}
$$

wherein $\alpha^{(i)}$ is a scalar representing a regularization coefficient allowing to take into account a balance between interference and useful signal after channel inversion, and allowing optimizing the Signal-to-Interference-plus-Noise Ratio (SINR), and wherein $\alpha^{(i)}$ is optimized according to statistics of the view $\mathbf{H}^{(i)}$ of the global MIMO channel $\mathbf{H}$ from the standpoint of the considered j-th transmitter among the $K$ transmitters, and wherein $\alpha^{(i)}$ is shared by said j-th transmitter with the other transmitters among the $K$ transmitters, and wherein $\alpha^{(i)}$ is obtained for example as in the document "Regularized Zero-Forcing for Multiantenna Broadcast Channels with User Selection", Z. Wang et al., IEEE Wireless Communications Letters, vol. 1, no. 2, pp. 129-132, April 2012, and wherein $\mathbf{V}^{(i)}$ is such that the refinement function $f(\cdot, \cdot)$ is used in the aforementioned additive refinement strategy, which means:

$$
\mathbf{v}^{(i)} = \mathbf{P}_k^{(i) o\alpha} \mathbf{F}_k^{(i)}
$$

by using a Monte Carlo simulation, or by using a numerical integration, on the distribution of $\Delta^{(1)}$, $\Delta^{(2)}$, ..., $\Delta^{(K)}$, which matches the long term statistics of CSIT error as obtained in the step S301, further with respect to the view $\mathbf{H}^{(o)}$ of the
global MIMO channel $H$ from the standpoint of the transmitter $120a$ (considered as the $j$-th transmitter among the $K$, transmitters).

[0138] Therefore, optimization of a figure of merit being a function of $\text{EMSE}_k^{(j)}$, such as the sum rate lower bound $\text{LBSR}^{(j)}$ or $\text{MNMSSE}_k^{(j)}$, according to the mathematical expectation of the realization of the estimate errors $\Delta^{(1)}, \Delta^{(2)}, \ldots, \Delta^{(K)}$ which matches the long terms statistics of CSIT error as obtained in the step S301, leads to obtaining the appropriate set $\{F_k^{(j)}\}$ of the refinement matrices $F_k^{(j)}$ by $k = 1$ to $K$, and then to obtaining the refined precoder $\mathbf{V}$ from said appropriate $\{F_k^{(j)}\}$ of the refinement matrices $F_k^{(j)}$ by applying the aforementioned additive refinement strategy.

[0139] In a preferred embodiment, an optimized sum rate lower bound $\text{LBSR}^{(j)}$ is obtained thanks to the iterative algorithm as detailed hereafter with regard to FIG. 4.

[0140] FIG. 4 schematically represents an algorithm for determining the refinement matrices $F_k^{(j)}$ from an optimization of $\text{LBSR}(j)$ and thanks to the above descriptions on how to compute $\text{EMSE}_k^{(j)}(F_k^{(j)}), \ldots, F_k^{(j)}$). The algorithm of FIG. 4 is performed by each and every $j$-th transmitter among the $K$, transmitters. Let’s illustratively consider that the algorithm of FIG. 4 is performed by the transmitter $120a$, considered as the $j$-th transmitter among the $K$, transmitters.

[0141] It is considered, when starting executing the algorithm of FIG. 4, that the transmitter $120a$ knows the matrices $\hat{\Sigma}_k^{(j)}, \Sigma_k^{(j)}$ and $\hat{H}_k^{(j)}$ for any and all $k$-th receiver among the $K$, receivers. The initialization can be set as random under the following constraint:

$$\text{Trace}(F_k^{(j)} F_j^{(j)}) = N$$

[0143] Alternatively, the refinement matrices $F_k^{(j)}$ are taken as identity $N \times N$ matrices for the block diagonal case, and $\text{MK}_k N \times N$ matrices containing only zeros for the regularized zero forcing case.

[0144] In a following step S402, the transmitter $120a$ computes $B^{(j)}$, for each and every $k$-th receiver among the $K$, receivers, such that:

$$B^{(j)} = \text{EMSE}_k^{(j)}(F_k^{(j)}, \ldots, F_k^{(j)})$$

[0145] In a following step S403, the transmitter $120a$ adjusts the refinement matrices $\{F_k^{(j)}\}$, for each and every $k$-th receiver among the $K$, receivers, as follows:

$$F_k^{(j)} = \arg \min A_{11}, \ldots, A_{K}, \ldots, \text{Trace} \left[ R_k^{(j)} \cdot \text{EMSE}_k^{(j)}(A_1, \ldots, A_k) \right]$$

such that the following constraint is preferably met:

$$\text{Trace}(F_k^{(j)} F_j^{(j)}) = N$$

[0146] In a following step S404, the transmitter $120a$ checks whether convergence has been reached with respect to $F_1^{(j)}, \ldots, F_k^{(j)}$, for each and every $k$-th receiver among the $K$, receivers. If such convergence has been reached, a step S405 is performed in which the algorithm of FIG. 4 ends; otherwise, the step S402 is repeated, in which $B_k^{(j)}$ is updated thanks to the values of $F_1^{(j)}, \ldots, F_k^{(j)}$ obtained in the last occurrence of the step S403.

[0147] The optimization of $\text{MNMSSE}^{(j)}$ can also be done in order to determine the refinement matrices $F_k^{(j)}$ thanks to the above descriptions on how to compute $\text{EMSE}_k^{(j)}(F_1^{(j)}, \ldots, F_k^{(j)})$. This leads to a convex optimization problem.

1-12. (canceled)

13. A method for performing transmissions of data between a plurality of $K$, transmitters and a plurality of $K$, receivers via a global MIMO channel $H=\{H_1, \ldots, H_K\}$ of a wireless communication system, by determining in a distributed fashion precoders to be applied for performing said transmissions, said precoders being respectively applied by said transmitters and jointly forming an overall precoder $\mathbf{V}$, wherein each and every $j$-th transmitter among said plurality of $K$, transmitters performs:

obtaining short-term CSIT related data and building its own view $\mathbf{H}(j)$ of the global MIMO channel $H$;

determining an estimate $\hat{V}_k^{(j)}$ of the overall precoder $\mathbf{V}$ from the obtained short-term CSIT related data; wherein said $j$-th transmitter further performs:

gathering long-term statistics of Channel State Information at Transmitter CSIT errors incurred by each one of the $K$, transmitters with respect to the global MIMO channel $H$, the long-term statistics describing the random variation of the CSIT errors;

refining the estimate $\hat{V}_k^{(j)}=\{\hat{V}_1^{(j)}, \ldots, \hat{V}_K^{(j)}\}$ of the overall precoder $\mathbf{V}$ on the basis of the gathered long-term statistics of CSIT errors so as to obtain a refined precoder $\hat{V}_k^{(j)}=\{\hat{V}_1^{(j)}, \ldots, \hat{V}_K^{(j)}\}$ that is a view of the overall precoder $\mathbf{V}$ from the standpoint of said $j$-th transmitter, further on the basis of its own view $\mathbf{H}(j)$ of the global MIMO channel $H$ and further on the basis of a figure of merit representative of performance of said transmissions via the global MIMO channel $H$; and

transmitting the data by applying a precoder that is formed by a part of the refined precoder $\hat{V}_k^{(j)}$ which relates to said $j$-th transmitter among said plurality of $K$, transmitters.

14. The method according to claim 13, wherein the figure of merit is a lower bound of a sum rate $\text{LBSR}^{(j)}$ reached via the global MIMO channel $H$, from the standpoint of said $j$-th transmitter with respect to its own view $\mathbf{H}(j)$ of the global MIMO channel $H$, as follows:

$$\text{LBSR}^{(j)} = \sum_{i=1}^{K_j} \text{EMSE}_i^{(j)}(F_1^{(j)}, \ldots, F_{K_j}^{(j)})$$

wherein

$$\text{EMSE}_i^{(j)}(F_1^{(j)}, \ldots, F_{K_j}^{(j)}) = \mathbb{E}[\text{Trace}(EMSE_i^{(j)}(F_1^{(j)}, \ldots, F_{K_j}^{(j)}))]$$

such that $F_k^{(j)}$, $k=1$ to $K$, are refinement matrices, and wherein $\mathbb{E}$ represents the mathematical expectation and, wherein $\text{EMSE}_i^{(j)}(F_1^{(j)}, \ldots, F_{K_j}^{(j)})$ represents mean square error matrix between the data to be transmitted and a corresponding filtered received vector for a realization of estimate errors $\Delta^{(1)}, \Delta^{(2)}, \ldots, \Delta^{(K)}$ which matches the long terms statistics of CSIT errors.

15. The method according to claim 13, wherein the figure of merit is the sum of traces $\text{MNMSSE}^{(j)}$, for $k=1$ to $K$, of $\text{EMSE}_i^{(j)}(F_1^{(j)}, \ldots, F_{K_j}^{(j)})$, as follows:
\[
\min \text{MSE}^{(j)} = \sum_{k=1}^{K} \text{Trace}(\text{EMSE}^{(j)}(F_k^{(1)}, \ldots, F_k^{(J)}))
\]

wherein \( F_k \), \( k = 1 \) to \( K \), are refinement matrices, and wherein \( \mathbb{E} \) represents the mathematical expectation and, wherein \( \text{MSE}^{(j)}(F_k^{(1)}, \ldots, F_k^{(J)}) \) represents the mean square error matrix between the data to be transmitted and a corresponding filtered vector for a realization of estimate errors \( \Delta^{(1)}, \Delta^{(2)}, \ldots, \Delta^{(K)} \) which matches the long term statistics of CSI errors.

16. The method according to claim 13, wherein refining the estimate \( \tilde{V}^{(j)} \) of the overall precoder \( V \) is performed thanks to a refinement function \( \mathcal{F}(\cdot, \cdot) \), as well as a set \( \{ F_j^{(j)} \} \) of refinement matrices \( F_j^{(j)} \), \( k = 1 \) to \( K_{\text{r}} \), in a multiplicative refinement strategy, as follows:

\[
V_j^{(0)} = \mathcal{F}(V_j^{(1)}, F_j^{(1)}; \ldots; V_j^{(K_{\text{r}})}, F_j^{(K_{\text{r}})}) - V_j^{(0)} / F_j^{(0)}
\]

17. The method according to claim 16, wherein the overall precoder \( V \) is a block-diagonalization precoder, the transmitters have cumulatively at least as many antennas as the receivers, and in that refining the estimate \( \tilde{V}^{(0)} \) of the overall precoder \( V \) thus consists in optimizing the set \( \{ F_j^{(j)} \} \) of the refinement matrices \( F_j^{(j)} \) with respect to the set \( \{ V_j^{(j)} \} \) of the matrices \( V_j^{(j)} \), which is obtained by applying a Singular Value Decomposition operation as follows:

\[
H_{\mathcal{F}}^{(0)}[\mathcal{V}^{(0)}][D_1^{(0)}; \ldots; D_{K_{\text{r}}}^{(0)}][P_0^{(0)} F_0^{(0)}]
\]

wherein \( H_{\mathcal{F}}^{(0)} \) represents a view of an aggregated interference channel estimation \( H_{\mathcal{F}}^{(0)} \) for the \( k \)-th receiver from the standpoint of said \( j \)-th transmitter, with

\[
H_{\mathcal{F}}^{(0)} = [H_1^{(0)} \ldots H_{K_{\text{r}}}^{(0)}]^{T}
\]

wherein \( \tilde{V}_j^{(j)} \) is obtained by selecting, according to a predefined selection rule similarly applied by any and all transmitters, a predetermined set of \( N \) columns of the matrix \( \tilde{V}_j^{(j)}(\cdot, \cdot) \) resulting from the Singular Value Decomposition operation, wherein each receiver has a quantity \( N \) of receive antennas.

18. The method according to claim 16, wherein the overall precoder \( V \) is an interference aware coordinated beamforming precoder with block-diagonal shape, \( K_{\text{r}} \), and each transmitter has as a quantity \( M \) of transmit antennas equal to a quantity \( N \) of receive antennas of each receiver, each transmitter communicates only with a single receiver among the \( K_{\text{r}} \) receivers such that \( k \neq j \), wherein a sub-matrix \( W_k \) such that:

\[
W_k = E_k W_k
\]

is computed as the eigenvector beamforming of the channel matrix defined by \( E_k F_k^{(0)} V_j^{(0)} \) from a Singular Value Decomposition operation applied onto said channel matrix defined by \( E_k F_k^{(0)} H^{(0)} E_k \), as follows:

\[
E_k F_k^{(0)} E_k^{T} D_j W_k
\]

wherein \( E_k \) is defined as follows:

\[
E_k = \text{diag}(a_1, 0, 0, \ldots, 0) I_{M \times M_{\text{r}}} a_k^{(0) T}
\]

with \( 0_{M \times (k-1) M} \) an \( M \times (k-1) M \) sub-matrix containing only zeros, \( 0_{M \times (K_{\text{r}}-k) M} \) an \( M \times (K_{\text{r}}-k) M \) sub-matrix containing only zeros, and \( I_{M \times M} \) an \( M \times M \) identity sub-matrix.

19. The method according to claim 13, wherein refining the estimate \( \tilde{V}^{(0)} \) of the overall precoder \( V \) is performed thanks to a refinement function \( \mathcal{F}(\cdot, \cdot) \), as well as a set \( \{ F_j^{(0)} \} \) of refinement matrices \( F_j^{(0)} \), \( k = 1 \) to \( K_{\text{r}} \), in an additive refinement strategy, as follows:

\[
V_j^{(0)} = \mathcal{F}(V_j^{(1)}, F_j^{(0)}; \ldots; V_j^{(K_{\text{r}})}, F_j^{(K_{\text{r}})}) - V_j^{(0)} / F_j^{(0)}
\]

20. The method according to claim 19, wherein the overall precoder \( V \) is a regularized zero-forcing precoder, and the estimate \( \tilde{V}^{(0)} \) of the overall precoder \( V \) can be expressed as follows:

\[
\tilde{V}^{(0)} = \mathcal{F}(V_j^{(1)}, F_j^{(0)}; \ldots; V_j^{(K_{\text{r}})}, F_j^{(K_{\text{r}})})
\]

wherein \( \alpha \) is a scalar representing a regularization coefficient that is optimized according to statistics of the own view \( H_j^{(0)} \) of the global MIMO channel \( H \) from the standpoint of said \( j \)-th transmitter, and wherein \( \alpha \) is shared by said \( j \)-th transmitter with the other transmitters among the \( K_{\text{r}} \) transmitters.

21. The method according to claim 13, wherein refining the estimate \( \tilde{V}^{(0)} \) of the overall precoder \( V \) performed under the following power constraint:

\[
\text{Trace}(\mathcal{F}(V_j^{(1)}, F_j^{(0)}; \ldots; V_j^{(K_{\text{r}})}, F_j^{(K_{\text{r}})})) \leq N
\]

wherein \( \mathcal{F}(\cdot, \cdot) \) is a refinement function and \( F_j^{(0)} \), \( k = 1 \) to \( K_{\text{r}} \) are refinement matrices, and wherein each receiver has a quantity \( N \) of receive antennas.

22. A non-transitory computer readable storage medium, wherein it stores a computer program comprising program code instructions which can be loaded in a programmable device for implementing the method according to claim 13, when the program code instructions are run by the programmable device.

23. A device for performing transmissions of data between a plurality of \( K_{\text{r}} \) transmitters and a plurality of \( K_{\text{r}} \) receivers via a global MIMO channel \( H = [H_1, \ldots, H_{K_{\text{r}}} \ldots H_{K_{\text{r}}} \ldots H_{K_{\text{r}}} \ldots] \) of a wireless communication system, by determining in a distributed fashion precoders to be applied for performing said transmissions, said precoders being respectively applied by said transmitters and jointly forming an overall precoder \( V \), wherein said device is each and every \( j \)-th transmitter among said plurality of \( K_{\text{r}} \) transmitters and comprises a processor configured to:

- obtain short-term CSI related data and building its own view \( H_j^{(0)} \) of the global MIMO channel \( H \);
- determine an estimate \( \tilde{V}^{(0)} \) of the overall precoder \( V \) from the obtained short-term CSI related data;
- characterized in that said device further comprises the processor configured to:
  - gather long-term statistics of Channel State Information at Transmitter CSI errors incurred by each one of the \( K_{\text{r}} \) transmitters with respect to the global MIMO channel \( H \), the long-term statistics describing the random variation of the CSI errors;
  - refine the estimate \( \tilde{V}^{(0)} = [\tilde{V}_1^{(0)}, \ldots, \tilde{V}_{K_{\text{r}}}^{(0)}] \) of the overall precoder \( V \) on the basis of the gathered long-term statistics of CSI errors so as to obtain a refined precoder \( \tilde{V}^{(0)} = [\tilde{V}_1^{(0)}, \ldots, \tilde{V}_{K_{\text{r}}}^{(0)}] \) that is a view of the overall precoder \( V \) from the standpoint of said \( j \)-th transmitter, further on the basis of its own view \( H_j^{(0)} \) of the global MIMO channel \( H \), and further on the basis...
of a figure of merit representative of performance of said transmissions via the global MIMO channel $H$; and transmit the data by applying a precoder that is formed by a part of the refined precoder $V^0$, which relates to said $j$-th transmitter among said plurality of $K$, transmitters.
